PCT

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Signed

Dated 6 August 1998

**Warning**

*After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.*

**Notes**

- a) If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- b) Write your answers in capital letters using black ink or you may type them.
- c) If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- d) If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- e) Once you have filled in the form you must remember to sign and date it.
- f) For details of the fee and ways to pay please contact the Patent Office.

## INDUSTRIAL FABRICS AND METHOD OF TREATMENT

This invention relates to industrial fabrics and to a method of treating such fabrics during the manufacture thereof to impart desired characteristics to the fabric.

The invention relates for example to all forms of paper making machine fabrics including dryer fabrics, press felts, including extended nip press belts, shoe press sleeves, corrugator machine press belts, and also to conveyor belts, printing blankets, silicon wafer grinding belts and filter cloths.

These fabrics may be treated for example to influence the wetting characteristics of the fabric, or in a composite fabric of two or more layers, of at least one layer of the fabric. Thus it is known e.g from US 5372876, to provide eg a papermaking felt which includes a flow control layer formed of a porous hydrophobic material. Conversely, EP-A-0761872 discloses a dryer fabric having a paper side contact surface which is hydrophilic, to improve adhesion between the paper web and the dryer fabric.

In both cases, the hydrophilic or hydrophobic properties of the layer or surface are achieved by coating or chemical treatment by application of the relevant compositions in a liquid medium.

As a method and means for treating substrates to influence their surface characteristics, the technology of plasma treatment is in the process of being developed. A 'plasma' is a fluid state of matter wherein due to excitation, the matter is present in the form of positive and negative ions. Polar molecules may be dissociated into anionic and cationic radicals, whilst free atoms lose electrons to form free electrons and positively charged atoms - depending upon the degree of excitation, more than one electron may be stripped from atomic shells. Plasmas can exist over an

extremely wide range of temperature and pressure; from over atmospheric to near vacuum. Because matter in the plasma exists in the form of charged ions, the plasma environment is extremely chemically energetic, and it has been proposed to treat the surfaces of materials by exposure to plasmas of selected composition.

It is an object of the present invention to provide fabrics for use in industrial processes, such as in paper making machines, conveyor belts, printing blankets and filtration fabrics by way of non-limiting example, which have had surface properties modified by plasma treatment, as an economical and environmentally improved alternative to treatment or coating with a liquid medium.

According to the invention an industrial fabric comprises or includes a layer or component which has been subjected to plasma treatment.

From another aspect the invention provides a method of making or preparing an industrial fabric including the step of subjecting at least one surface of a layer or component of the fabric to plasma treatment.

The invention also includes apparatus for use in making or preparing an industrial fabric, including a plasma chamber to which material comprising or for use in making said fabric may be introduced, and removed after treatment.

The purpose of the plasma treatment may be to modify the wetting characteristics of the surface being treated, i.e. to render the surface hydrophobic or hydrophilic.

Alternatively the surface is provided with activated sites to improve subsequent coating or dyeing. This treatment may utilise glow discharge dielectric barrier discharge or spray discharge plasma. Compared with corona discharge treatment techniques the modified characteristics of the treated surface are permanent and far

more durable.

Other characteristics can be enhanced by appropriate choice of composition of the plasma, e.g. improved softness in drying felts especially for tissue making machines, crease resistance and antistatic properties.

In a preferred method of the invention, hydrophilic properties are enhanced by subjecting the surface to a plasma comprising or containing oxygen, air or ammonia for example.

In another preferred method of the invention, hydrophobic properties are enhanced by subjecting the surface to a plasma comprising or containing a silane, e.g.  $\text{Si}(\text{CH}_3)_4$ , a siloxane, e.g.  $(\text{Si}(\text{OCH}_3)_2)_4$  or a perfluorocarbon, e.g. 1-6C perfluoroalkane or tetrafluoroethylene or a combination thereof.

Hard coatings of e.g. carbon may be formed by subjecting the surface to a plasma comprising or containing hydrocarbon e.g. methane. Heat resistant coatings can be applied by using a plasma comprising or containing halogenated hydrocarbons or unsaturated amines (e.g. tetrachloroethylene; 1,1,2-trichloroethane; allylamine or trichloroethylene). The plasma may be diluted with a diluent gas such as helium.

The material may be treated in the form of a ready made up layer or web or as fibres or yarns prior to weaving or making up the layer.

The apparatus of the invention may comprise means for continuously introducing the material into the plasma chamber, moving the material through the chamber during treatment, and causing it to leave the chamber after treatment. Alternatively the material may be introduced to the plasma chamber in batches, which are subjected to treatment and then removed.

The operating pressure of the plasma chamber may be from in the order of 0.1 -

3.0 mbar, up to and above 1 atmosphere.

A preferred embodiment of the invention will now be described by way of example, and with reference to the accompanying drawing, which is a diagrammatic view of a plasma treatment machine according to the invention.

In the preferred embodiment, a fabric 10 eg a woven or non-woven web destined to form all or part of an industrial fabric such as a paper machine press felt, dewatering drying or forming belt, is fed from a dispensing station 11. This is shown simply as a feed roll, but would in practice include guide and compensating devices in addition, as is well known in the art. The fabric 10 is introduced through a self-sealing entry slot 12 into a plasma chamber 13, and exits through a similar self-sealing exit slot 14 after passing through the plasma chamber and being subjected to plasma treatment within the chamber. The treated fabric 10 is then taken up on a winding station 15 which is shown as a simple take up roll, but in practice would include such guide and compensating apparatus as is required, as is well known in the art.

The fabric 10 enters and leaves the chamber 13 through self-sealing slots 12 and 14 as the plasma usually operates at a considerable under-pressure, often extremely rarified, e.g. 0.1 - 3.0 mbar; and sometimes contains components which must not be allowed into the ambient.

To achieve plasma conditions, the chamber 13 is evacuated to the required pressure by pump means acting under pressure control 16. The material to form the plasma is introduced at 17, and excitation proceeds by the creation of an intense electrical field between electrodes 18, 19 subject to a controller 20. The plasma is created by ionising the molecules or atoms of the plasma forming material to form ionised radicals, or to provide free electrons and positively charged atoms.

Treatment is achieved by exposing one or both surfaces of the fabric to the plasma within chamber 13.

The composition of the plasma will be selected in accordance with the objective of the treatment. For example, to improve wettability (hydrophilic) properties of a fabric, the plasma may be created from ordinary air, oxygen, ammonia or a mixture of these.

To provide a water-repellant finish (hydrophobic) the plasma may be created from a siloxane or perfluorocarbon compound.

Examples of other properties which may be enhanced by such plasma treatment are softness (oxygen plasma), crease resistance (dipped in DMSO, then exposed to nitrogen plasma); anti-static finish - chloro (chloromethyl) dimethylsilane plasma; oil repellent finishes, improvement of capillarity, dye reception, dyeing depth, bleaching, UV-protection and flame retardancy may also be provided for.

The fabric may instead of being fed continuously as illustrated, be placed in the machine in batches, treated and then removed. The fabric may be placed on a conveyor to be fed through the chamber, or associated with a backing layer when only one surface is to be treated.

The material to be treated may be in the form of fibres or yarns prior to making up into a woven or nonwoven fabric and such are particularly suited to a conveyor feed, or to batch treatment e.g in mesh cages which can be introduced to and removed from the plasma chamber.

A hydrophobic (water repellent) fabric may be used as a flow control layer in a paper making felt of the kind described in US, 5,372,876, whilst a hydrophilic (with enhanced wettability) fabric may be used as a dryer fabric such as described in EP-A-

0761872 mentioned above.

The term 'fabric' as used above should be interpreted to cover sintered felts, coatings of coated papermaking fabrics, non wovens and films, spiral link structures, membranes or polymer matrix material and their components prior to making up where appropriate e.g. sintered particles.

The speed of material being fed into the chamber in the illustrated version may be 5 - 100 metres per minute. At present working widths are limited to about 2.7 metres. The development of larger machines capable of treating greater web widths is hindered by the practical difficulties associated in maintaining a sufficient vacuum in a larger chamber. It is thus often more convenient to treat yarns and fibres or other fabric constituents rather than finished fabrics.

A hydrophilic surface for a dryer fabric, as in EP-A-0761872 obtains improved adhesion between the dryer fabric and the paper web. A hydrophobic surface may be desirable for certain dryer fabrics for contaminant release, whilst forming fabrics may be rendered hydrophobic for the same reasons or may be hydrophilic to improve drainage. It is believed that a very thin film of water is attracted to the surface of the yarns in the fabric providing "lubrication" for water flowing through the interstices of the fabric. Batt staple fibres in press felts can be rendered hydrophilic to make the felts absorb water better initially, improving the conditioning of the felt and thereby reducing start up times. However, a layer of hydrophobic batt staple fibres (or base cloth yarns) within the felt can form an anti-rewetting or flow control layer, which hinders the return flow to the web of water which has initially been urged into the felt from the paper (as in US 5372876).

A further possible use of the invention is by plasma treatment of yarns, fibres,

films or membranes used to reinforce polymer matrices to form belts, such as extended nip press belts, shoe press sleeves, press belts for corrugator machines, conveyor belts, printing blankets, silicon wafer grinding belts, or carcass stripping belts. The activated groups formed on the reinforcing substrate surfaces improve bonding with the matrix polymer. This is particularly useful for reinforcing a polyurethane matrix with polyester structural members such as yarns, fibres or fabrics (woven, nonwoven spiral link or membrane), the latter having excellent dimensional stability but poor adhesion to polyurethane. Adhesion may be improved by a factor of 2 - 3. For this purpose ammonia or nitrogen plasmas are preferred. Yarns, fibres, films, membranes or finished fabrics may be treated by plasma according to the invention to provide hydrophobic coatings for filter cloths (especially those used in dust filtration) to improve cake release.

Plasma treatment as outlined above has the advantages that the process is solvent free, (including no use of water), very small amounts of the raw materials are required (eg 30-100 mg per m<sup>2</sup> fabric); energy consumption is low, as no water is used which absorbs heat; labour costs are negligible, as the process can be automated, and the overall cost per unit area of fabric can be very low.

The invention is applicable to all industrial fabrics, including conveyor belts and filter cloths, but is mainly directed to all forms of paper machine clothing.
